## 1 Semaphores

### 1.1 Disadvantages of synchronisation by communication

- complex algorithms
- time wasting — busy waits
- primitive (atomic) actions are too weak

We need an atomic read/write action, and a mechanism to allow processes to “sleep” — semaphores.

### 1.2 Semaphores

Introduced by *Edsger Dijkstra*.

**P()** *Passeren* (Pass)

[A better name might be *prolagen*, from *proberen* (try) and *verlagen* (reduce)].

**V()** *Vrijgeven* (Free)

English mnemonic — **P**oll and **V**ote

A process that calls *P()* when  $s = 0$  can only complete the call when  $s \neq 0$ , after a *V()* operation — they must “sleep”.

The order in which processes are woken is unspecified, but it must be *fair*.

### 1.3 Binary and split binary semaphores

**Binary semaphore:**

Can only take values 0 or 1

$$0 \leq s.\text{value}() \leq 1$$

**Split binary semaphore:**

*Total* value is 0 or 1

$$0 \leq s_1.\text{value}() + s_2.\text{value}() \leq 1$$

Properties can be *programmer's* responsibility — but sometimes only binary (split) semaphores provided.

## 2 Producer/Consumer

### 2.1 Introduction

Models many “buffering” problems

- Producer produces data, snacks, sproglets, ...
- Consumer consumes data, snacks, sproglets, ...
- Buffer
  - synchronises exchange
  - “smooths out” speed differences
- Initial assumptions
  - infinite buffer
  - simultaneous access for producer/consumer
- Later
  - access to buffer in critical section
  - finite buffer — bounded buffer problem

### 2.2 The producer and consumer

| producer: buffer.put(item)   | consumer: buffer.get()   |
|--|--|
| <pre> public void producer() {     while (true) {         // build item to add         buffer.put(item);     } }</pre> | <pre> public void consumer() {     while (true) {         T item = buffer.get();         // do something with item     } }</pre> |

### 2.3 Basic algorithm

infinite buffer, simultaneous access

| producer: buffer.put(item)   | consumer: buffer.get()   |
|--|--|
| <pre> public void put(T item) {     putItem(item);     noOfElements.V(); }</pre> | <pre> public T get() {     noOfElements.P();     T item = getItem();     return item }</pre> |

Here `noOfElements.value()` = no. of elements in buffer.

The producer will first add an element, and then increase `noOfElements` with a “V”. The consumer first tests for an empty buffer, and only then takes an element.

## 2.4 Forbidding simultaneous access

putItem and getItem in critical section

| producer: buffer.put(item)  | consumer: buffer.get()   |
|---|--|
| <pre> public void put() {     criticalSection.P();     putItem(item);     criticalSection.V();     noOfElements.V(); } </pre> | <pre> public T get() {     noOfElements.P();     criticalSection.P();     T item = getItem();     criticalSection.V();     return item; } </pre> |

Initialise noOfElements = 0, criticalSection = 1. Note: order of criticalSection.P() and noOfElements.P() is essential (order of criticalSection.V() and noOfElements.V() — not important)

## 2.5 Bounded buffer

| producer: buffer.put(item)  | consumer: buffer.get()  |
|---|---|
| <pre> public void put() {     noOfSpaces.P();     criticalSection.P();     putItem(item);     criticalSection.V();     noOfElements.V(); } </pre> | <pre> public void get() {     noOfElements.P();     criticalSection.P();     T item = getItem();     criticalSection.V();     noOfSpaces.V();     return item; } </pre> |

# 3 Implementing Semaphores

## 3.1 class Semaphore: Fields

```

// Value of the semaphore
private int value = 0;

```

## 3.2 class Semaphore: Constructors

```

// Initialise value to default value of zero
protected Semaphore() {
    value = 0;
}

```

```

// Initialise to the specified value
protected Semaphore(int initial) {

```

## Semaphores

```
    value = initial;
}
```

### 3.3 class Semaphore: Methods

```
// Poll method
public synchronized void poll()
    throws InterruptedException {
    value--;
    if (value < 0) {
        wait()
    }
}

// Vote method
public synchronized void vote() {
    value++;
    if (value <= 0) {
        notify();
    }
}
```

### An Aside: **synchronized** Methods

A **synchronized** method is one that may only be executed by at most one process at any one time. Also, if a **synchronized** method is being executed, no other **synchronized** method belonging to the same object may be executed at the same time. In this example the **synchronized** methods will belong to a **Semaphore** object.

The **wait()** and **notify()** methods can be used to further refine processes' behaviour in **synchronized** methods:

- A process calling **wait()** will go to sleep, therefore ceasing to execute inside the **synchronized** method(s), and therefore allowing other processes to access these methods.
- The sleeping process will sleep until another process calls **notify()**. The process calling **notify()** will complete execution of the **synchronized** method normally. When it leaves the **synchronized** method the **waiting** process *may* be woken.

## 4 Bounded Semaphores

Semaphores with an upper limit as well as a lower one — e.g. binary semaphores. Three possibilities:

## Semaphores

### 4.1 Absorbing Semaphores

Once the semaphore reaches its limit it stops incrementing its value.

|     |      |   |     |       |     |       |       |
|-----|------|---|-----|-------|-----|-------|-------|
|     | 0    | 1 | ... | $i$   | ... | $N-1$ | $N$   |
| P() | wait | 0 | ... | $i-1$ | ... | $N-2$ | $N-1$ |
| V() | 1    | 2 | ... | $i+1$ | ... | $N$   | $N$   |

### 4.2 Crashing Semaphores

Once the semaphore reaches its limit any attempt to increase its value by a V() causes it to crash.

|     |      |   |     |       |     |       |       |
|-----|------|---|-----|-------|-----|-------|-------|
|     | 0    | 1 | ... | $i$   | ... | $N-1$ | $N$   |
| P() | wait | 0 | ... | $i-1$ | ... | $N-2$ | $N-1$ |
| V() | 1    | 2 | ... | $i+1$ | ... | $N$   | ⌂     |

### 4.3 Blocking Semaphores

Once the semaphore reaches its limit any attempt to increase its value by a V() causes it to block.

|     |      |   |     |       |     |       |       |
|-----|------|---|-----|-------|-----|-------|-------|
|     | 0    | 1 | ... | $i$   | ... | $N-1$ | $N$   |
| P() | wait | 0 | ... | $i-1$ | ... | $N-2$ | $N-1$ |
| V() | 1    | 2 | ... | $i+1$ | ... | $N$   | wait  |

## 5 Using Java Semaphores to Implement a Bounded Buffer

Need to `import java.util.concurrent.Semaphore;`

### 5.1 `class Buffer<T>: Fields`

```
private Semaphore noOfSpaces, noOfElements, criticalSection;
private T[] buffer;
private int putIndex = 0, getIndex = 0;
```

### 5.2 `class Buffer<T>: Constructor`

```
public Buffer(int size) {
    buffer = new T[size]; // can't actually do this in Java
    noOfSpaces = new Semaphore(size, true); // is fair
```

## *Semaphores*

```
noOfElements = new Semaphore(0);  
criticalSection = new Semaphore(1);  
}
```

### 5.3 `class Buffer<T>`: The put method

```
public void put(T item) {  
    try {  
        noOfSpaces.acquire();  
        criticalSection.acquire();  
        addItem(item);  
        criticalSection.release();  
        noOfElements.release();  
    } catch (InterruptedException ie) {  
        throw new BufferError("Data item not added\n" +  
            ie.getMessage());  
    }  
}
```

### 5.4 `class Buffer<T>`: The get method

```
public T get() {  
    try {  
        noOfElements.acquire();  
        criticalSection.acquire();  
        T item = getItem();  
        criticalSection.release();  
        noOfSpaces.release();  
        return item;  
    } catch (InterruptedException ie) {  
        throw new BufferError("Data item not fetched\n" +  
            ie.getMessage());  
    }  
}
```

### 5.5 `class Buffer<T>`: Update methods

```
private void addItem(T item) {  
    buffer[putIndex] = item;  
    putIndex = (putIndex + 1) % buffer.length;  
}
```

## *Semaphores*

```
private T getItem() {  
    T item = buffer[getIndex];  
    getIndex = (getIndex + 1) % buffer.length;  
    return item;  
}
```

End of semaphores lecture
