LOGBOOK

Algorithms – Processes and data

Practical 4 (Week 7)

(Logbook) Question 1: Implement the List<T> interface, using singly linked lists.

```
public SingleLinkList()
 * @param value the value with which to create the root node of the SingleLinkList.
```

```
/**
  * Returns the size of the list.
  *
  * @return the size of the list.
  */
public int getSize()
{
    return this.size;
}
```

```
* @param value the value to be added.
* @throws ListAccessError if the index is invalid in respect to the size of the list.
@Override
public void add(int index, T value) throws ListAccessError
   if(index < 0 | | index > size) { throw new ListAccessError("Invalid index location " + index); }
   SingleLinkNode<T> previous = getRoot();
    SingleLinkNode<T> nextAfterNew = previous.getNext();
    previous.setNext(newNode);
```

```
* @throws ListAccessError if the index is invalid in respect to the size of the list.
@Override
public T remove(int index) throws ListAccessError {
   SingleLinkNode<T> previousNewNext = getRoot().getNext();
   T removed = get(index);
       setRoot(previousNewNext);
       return removed;
   previousNewNext = previousNewNext.getNext();
       previousNewNext = previousNewNext.getNext();
   previous.setNext(previousNewNext);
```

Test Class Code Listing.

```
import org.junit.jupiter.api.Test;
import static org.junit.jupiter.api.Assertions.*;
  void testCreateSize0()
           fail("Root is not null");
```

```
#Test
void testCreateSizel()
{
    SingleLinkList<Integer> intList = new SingleLinkList<>(2);

    if(intList.getRoot() == null)
    {
        fail("Root is null for some reason");
    }
    if(intList.getSize() != 1)
    {
        fail("Size of list is not 1.");
    }
}

### Prest
void testInitialNodeValue()
{
    SingleLinkList<Integer> intList = new SingleLinkList<>(1);

    //List = {1}

    if(intList.getRoot().getValue() != 1)
    {
        fail("Root value is not 1 for some reason");
    }
}
```

```
void testSizeWorks() throws ListAccessError
    intList.add(1, 2);
    intList.add(2, 3);
    intList.remove(0);
       fail("Size not correctly updated to 3");
    intList.remove(1);
       fail("Size not correctly updated to 2");
    intList.remove(1);
       fail("Size not correctly updated to 0");
```

```

       fail("Root value is not 2");
void testAddToListSizelAfterRoot() throws ListAccessError
   intList.add(1, 2);
       fail("Root value is no longer 1");
       fail("Value of 2 not correctly added to index 1");
```

```
void testAddToGenericInternalIndex() throws ListAccessError
   SingleLinkList<Integer> intList = new SingleLinkList<>(1);
    intList.add(1, 2);
    intList.add(2, 3);
       fail("List not set up correctly for test.");
       fail("Root node is no longer 1");
       fail("10 not added to index 1");
       fail("2 not correctly moved to index 2");
    if(intList.get(3) != 3)
       fail("Size not correctly updated to 4.");
```

```
void testAddToEndOfList() throws ListAccessError
   SingleLinkList<Integer> intList = new SingleLinkList<>(1);
    intList.add(1, 2);
    intList.add(2, 3);
       fail("List not set up correctly for test.");
    intList.add(3, 10);
       fail("3 no longer at correct index of 2");
    if(intList.get(3) != 10)
       fail("10 not added to end of list correctly.");
   if(intList.getSize() != 4)
       fail("Size not correctly updated to 4.");
void testRemoveIndexNegativeIndex() throws ListAccessError
```

```
void testRemoveIndexEqualToSize() throws ListAccessError
   SingleLinkList<Integer> intList = new SingleLinkList<>(1);
void testRemoveIndexGreaterThanSize() throws ListAccessError
       fail("Index of 2 not caught");
void testRemoveFromListSizelAtRoot() throws ListAccessError
   SingleLinkList<Integer> intList = new SingleLinkList<>(1);
    int removed = intList.remove(0);
   if(removed != 1)
       fail("Removed element value 1 not correctly returned.");
```

```
void testRemoveFromGenericInternalIndex() throws ListAccessError
   SingleLinkList<Integer> intList = new SingleLinkList<>(1);
    intList.add(1, 2);
    intList.add(2, 3);
       fail("List not set up correctly for test.");
       fail("3 not correctly moved down to index 1");
       fail("Size not correctly updated to 2.");
```

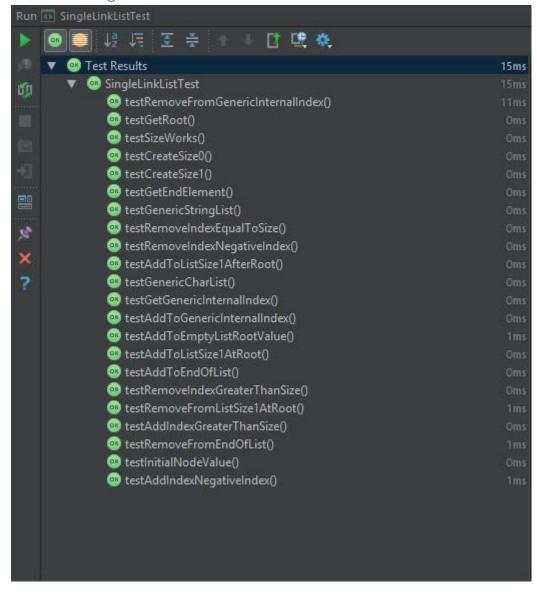

```
void testRemoveFromEndOfList() throws ListAccessError
   intList.add(1, 2);
       fail("List not set up correctly for test.");
       fail("Size not correctly updated to 2.");
```

```
void testGetRoot() throws ListAccessError
   SingleLinkList<Integer> intList = new SingleLinkList<>(1);
   intList.add(1, 2);
    intList.add(2, 3);
void testGetGenericInternalIndex() throws ListAccessError
   intList.add(1, 2);
    intList.add(2, 3);
       fail("Element value 2 not correctly returned");
void testGetEndElement() throws ListAccessError
   SingleLinkList<Integer> intList = new SingleLinkList<>(1);
   intList.add(1, 2);
```

```
void testGenericCharList() throws ListAccessError {
   charList.add(1, 'b');
    if(charList.getSize() != 3)
       fail("Root element not correctly changed to z");
   char removed = charList.remove(2);
       fail("List size not correctly updated to 3");
    if(charList.get(1) != 'a')
       fail("Next element no longer c");
       fail("Removed element value b not correctly returned.");
```

```
void testGenericStringList() throws ListAccessError {
    SingleLinkList<String> stringList = new SingleLinkList<>("aaa");
    stringList.add(1, "bbb");
   stringList.add(2, "ccc");
    if(stringList.getSize() != 3)
    if(stringList.getSize() != 4)
       fail("list size not correctly updated to 4");
    if(!(stringList.get(0).equals("zzz")))
       fail("Root element not correctly changed to zzz");
   if(!(stringList.get(1).equals("aaa")))
       fail("root element aaa not correctly moved to index 1");
   String removed = stringList.remove(2);
    if(stringList.getSize() != 3)
    if(!(stringList.get(1).equals("aaa")))
   if(!(stringList.get(2).equals("ccc")))
       fail("Next element no longer ccc");
   if(!(removed.equals("bbb")))
       fail("Removed element value bbb not correctly returned.");
```

Result of testing.

Self Evaluation.

The marking scheme lists 5 marks for a solution having Boundary checking and exceptions with the inclusion of a test suite.

My implementation implements boundary checking with exceptions at the start of all methods and includes a comprehensive test suite. Evidence for both can be found in the above three headings. My implementation further more includes boundary checking as part of its optimisation, reducing the number of checks and re-allocations required. This improves the efficiency of the implementation and allows it to scale up much further than other implementations.

(Additional) Question 1.5: Model answer comparison.

Model answer for Get method.

```
package linkedList.list;
import linkedList.node.ListNode;
.mport linkedList.node.SingleLinkNode;
public abstract class SingleLinkListModel<T> extends BasicList<SingleLinkNode<T>,T> implements List<T> {
   ListNode<T> getNode(int index) throws ListAccessError {
       if (index < 0) {
           throw new ListAccessError("Cannot get node. Negative index.");
       ListNode<T> currentNode = getRoot(); // start at the root
```

```
index--; // and reducing index by one
}
// Reached the end of the list (by hitting null node)? If so, cannot access the required node.
if (currentNode == null) {
    throw new ListAccessError("Cannot get node. Not enough nodes in the list.");
}
// Successfully found node by walking through until index was zero.
return currentNode;
}

/**
    * Access the value at a given index.
    *
    * @param index the index of the value to be accessed.
    * @throws ListAccessError if there is no value with the given index.
    */
public T get(int index) throws ListAccessError {
    return getNode(index).getValue();
}
```

My Implementation for Get method.

```
/**
 * Return the value of the element in the list at the index specified.

* * @ param index the index of the entry to be accessed.

* * @ return the value of the element at the index specified.

* * @ throws ListAccessError if the index is invalid in respect to the size of the list.

*/

@ Override
public T get(int index) throws ListAccessError

{
    //Make sure the index trying to be accessed is not invalid.
    if(index < 0 || index > size) { throw new ListAccessError("Invalid index location " + index); }

    //Set up a storage variable for the node being accessed.
    SingleLinkNode<T> get = getRoot();

    //Cycle through the list until the correct element has been found.
    for(int x = 1; x <= index; x++)
    {
        get = get.getNext();
    }

    //Return the element's value.
    return get.getValue();
}</pre>
```

Comparison.

One thing that is noticeable straight off the bat is the larger exception handling that the model answer includes at the top of the function. Despite the extra lines, the model answer handles initial exceptions in a slightly more user friendly way, giving the user/programmer information of the exact problem they've encountered, rather than my method which simply returns the invalid index.

The model answer also does exception handling during the 'walk-through' to find the node requested, whereas as mine does not. This is because my implementation for the SingleLinkList adds a recorded size of the list which is used during the initial error checking to make sure the programmer/user is not trying to access a data location past the end of the list. The model answer does not have this 'size' recording, therefore cannot do this check at the start of the method, bulking out the code and making it slightly less readable.

The perfect combination of error checking would be the inclusion of my size recording and initial error checking handling everything along with the model implementations user friendly exception reporting.

The exclusion of this error handling at the start has impacts upon the efficiency of the model solution, as when finding the correct node, additional checks have to be done each time a new element is attempted to be accessed. This check makes sure that the next element is not null before attempting to access it. My implementation however, can simply walk through without any possibility of reaching a null node. This is objectively better than the model implementation's approach as it improves code readability & maintainability and improves efficiency via reducing the amount of brute force checks that have to be made during the walk-through.

In conclusion, I'd state that the model answer outweighs my solution in terms of user experience, allowing easier bugfixing and smoother usage. This could arguably be a key factor given the abstract implementation nature of these exercises. However, my implementation takes the lead where efficiency is concerned. Despite this efficiency lead being very small given the computational power of systems today, my implantation would scale far better into a system the likes of which are developed and used today.

(Additional) Question 2: Write some test code that uses array generators to create large random arrays. Use the values in these arrays to populate instances of your implementation of linked lists. Now attempt multiple accesses of the data both in the arrays and in the lists.

```
package Comparison;
import arrayGenerator.generator.IntegerArrayGenerator;
mport arrayGenerator.scope.IntegerScope;
import linkedList.list.ListAccessError;
public class SingleLinkListComparison
   private static void timeComparison() throws ListAccessError
       Random rand = new Random();
       for(int arraySize = SIZE_OF_ARRAY; arraySize <= 1000000; arraySize *= 10 )</pre>
           Integer[] ints = new IntegerArrayGenerator(new IntegerScope()).getArray(arraySize);
           SingleLinkList<Integer> list = new SingleLinkList<>();
            for(int x = 0; x < arraySize; x++)</pre>
               list.add(x, ints[x]);
           System.out.println("Testing array of size: " + arraySize);
```

```
double before = System.nanoTime();
    int arrayInt = ints[i];
    System.out.println("System took " + ((System.nanoTime()) - before) + " ns. to access the array");
    before = System.nanoTime();
    int listInt = list.get(i);
    System.out.println("System took " + ((System.nanoTime()) - before) + " ns. to access the list.");
SingleLinkListComparison.timeComparison();
listAccessError.printStackTrace();
```

Test data.

This is an example of the test data I acquired from running the code listing above. There are 100 rows of recordings for each array size, however I have abbreviated the table size in the interests of brevity.

	100	10	000	10	000	100	0000	100	00000

Averages.
From this data I calculated the average access time for each data structure for each size of array tested.

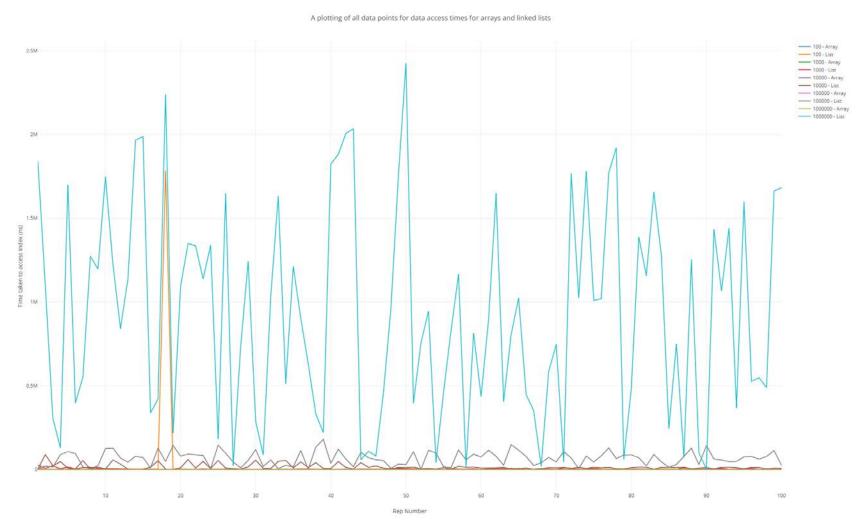

Averages	Array	List
100	484.7	19994.29
1000	467.55	3478.25
10000	379.14	15070.53
100000	484.7	66437.62
1000000	484.7	935018.2

Graph plotting.

All data points

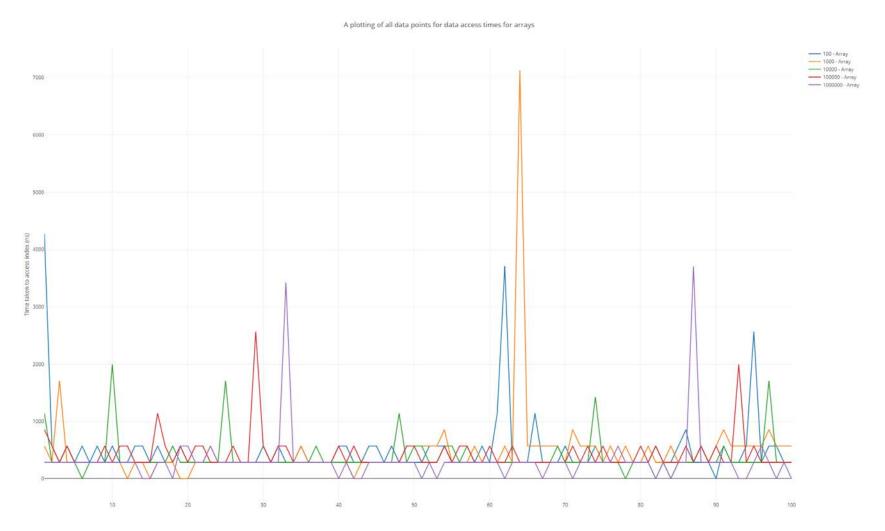

This graph shows every data point plotted. From this scale it is easy to see the constant access time of arrays from the traces near the bottom of the graph.

When the graph is scaled like this however, it becomes much easier to grasp just how badly the Linked List performs at higher element counts. The blue line on the graph plots the times for a Linked List of 1,000,000 elements and absolutely dwarfs everything beneath it. In comparison, the array trace for the same number of elements retains its constant access time.

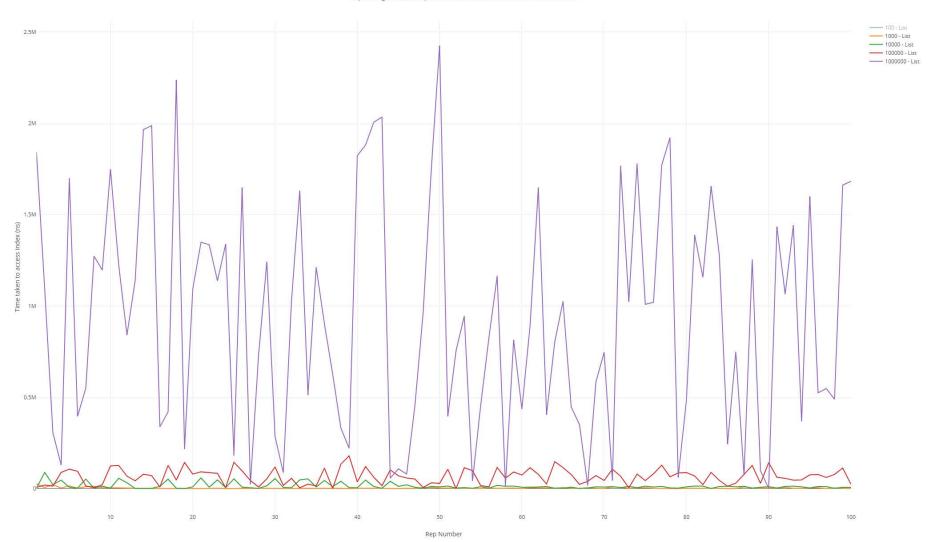

Array time comparisons.

This graph shows the times taken by the array to access the same data as the Linked List. As can be seen, the highest time recorded to access an index was taken by an array of size 1000. This proves that arrays are not affected by size in the same way that Linked Lists are when it comes to access time. Interestingly, the graph's visibly discrete Y values display the constant access time quite well, as there are no analogue values.

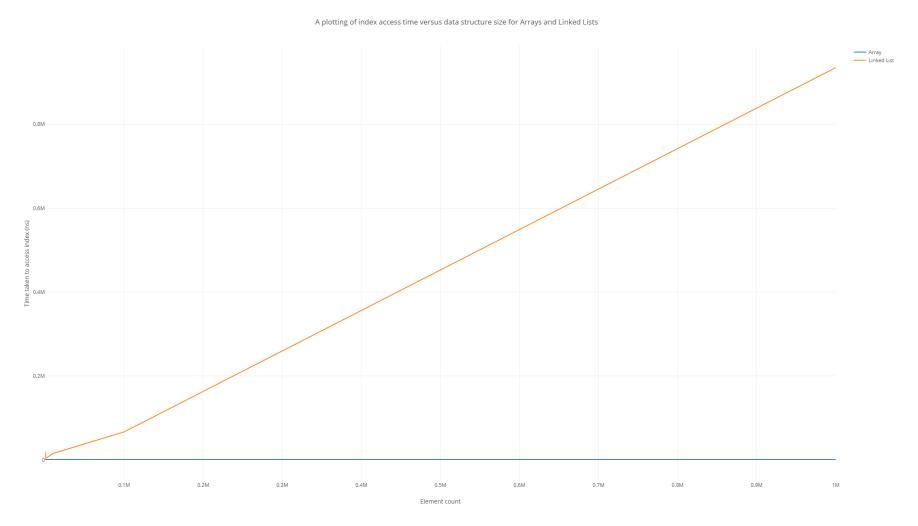

Linked List time comparisons.

A plotting of all data points for data access times for Linked Lists

This graph shows the times taken by Linked Lists to access the same data as the arrays. Each trace visibly increases its average up the Y axis, proving the Linked List dependence on element count. This graph, in stark contrast to the graph plotted for the array, shows the continuous/analogue performance of the Linked List. This also suggests a dependence on computer performance that is much higher than the arrays. This has an upper limit and Linked Lists will always be slower than arrays however, as Linked Lists still have to do operations before accessing a memory address whereas arrays can almost directly access a memory address. This means that however fast a CPU gets at processing these instructions, a Linked List will always be slower than an array for the same tasks.

Average Plots.

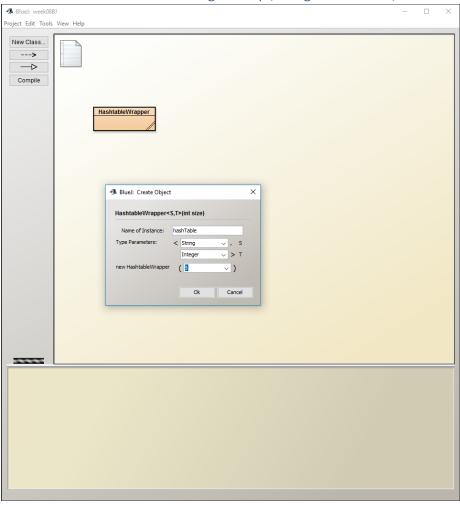

Finally, this graph (plotting the average access time per element count) shows the constant access time for Arrays very well. The graph may also suggest a linear relationship between data structure size and access time, however I am reluctant to outright state this as there are only 5 data point plotted on this graph, and the majority of the graph is taken up by the difference between 100,000 and 1,000,000 points.

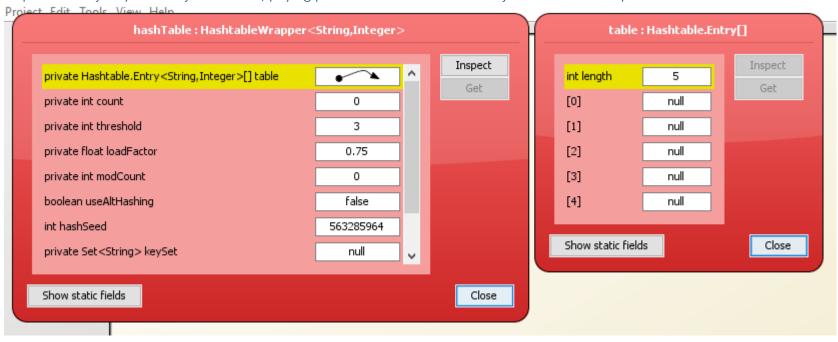

Practical 5 (Week 8)

(Logbook) Question1: Create an object instance of the HashtableWrapper(String, Integer) class.

Ensure this hash table uses Strings as keys, Integers as values, and has an initial size of 5.

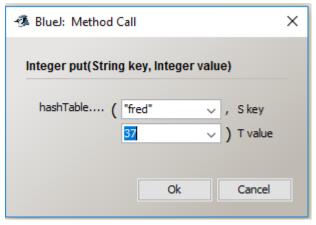

Inspect the object you have just created, paying particular attention to the object's internal array.

Some fields of note in this inspection might be the count of 0, (Stating the number of elements in the array) and each field in the internal array, showing that each entry is null and has nothing contained within.

Now, using the void put(String key, Integer data) method, add the key/value pair ("fred", 37) to the hashtable.

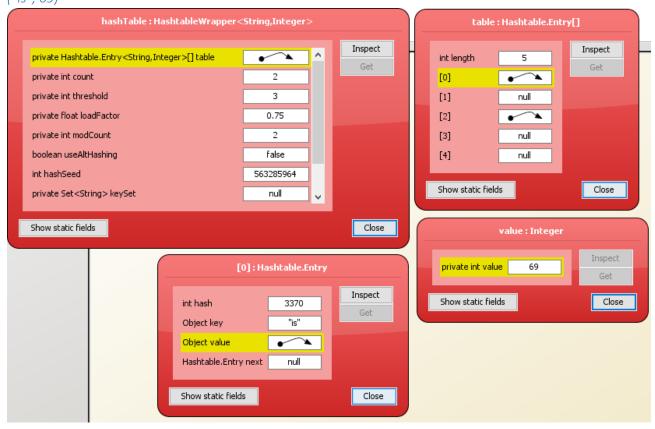

Inspect the object again.

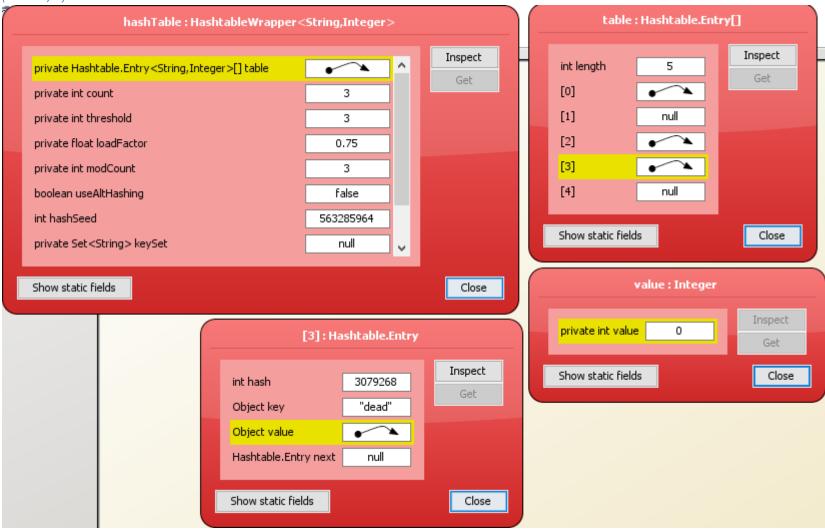

Fields of note here: The count field has changed to 1 to signify there is one element within the internal array. The internal array at index 2 contains a pointer to a 'Hashtable Entry' which contains the hash, key, next entry (for collisions) and a pointer to the actual value held. The modcount field has increased to 1.

Now add the following key/value pairs, again inspecting the hashtable object after each new pair is entered. ("is", 69)

The count field has changed to 2. The modcount field has increased to 2. Index 0 in the internal array contains a hashtable entry for ("is", 69).

("dead", 0)

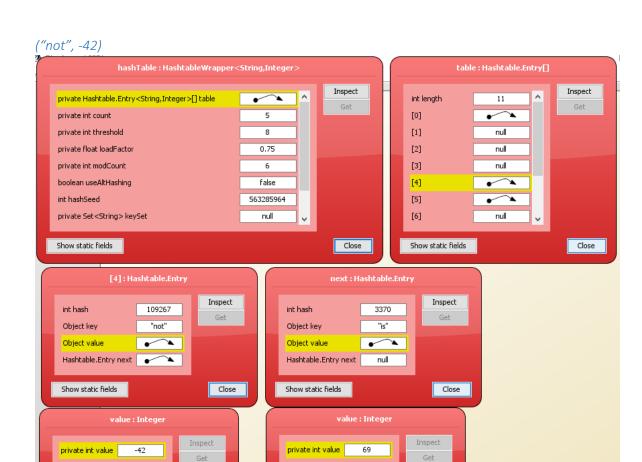

The count field has increased to 3, the modcount field has increased to 3. Index 3 contains a pointer to a hashtable entry for ("dead", 0).

("but", 999)

Value	Old Index	New Index
("fred", 37)	2	0
("is", 69)	0	4
("dead", 0)	3	5

The count field has increased to 4. The threshold field has increased to 8. This is perhaps due to count reaching the value of threshold, upon which the hashtable realises it needs to increase the size of its internal array. The value of modCount has increased to 5. The hashtable entries have also been moved around, however I'm unsure exactly as to how the Hashtable class has determined this.

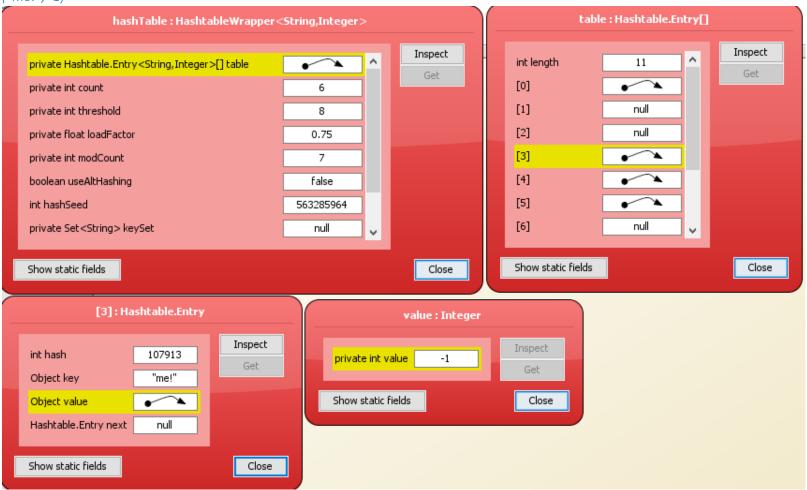

Show static fields

Show static fields

Close

Count has increased to 5. Modcount has increased to 6. The new hashtable entry has fallen on the index of ("is", 69), so the new hashtable entry has taken its place, and kicked ("is", 69) down a place so that ("not", -42) is the first visible entry in the internal array and ("is", 69) resides at the second layer.

("me!", -1)

Count has increased to 6. Modcount has increased to 7. Otherwise, ("me!", -1) has been treated very much like a standard hashtable entry, taking the until now empty index of 3.

Additional explanation.

For each key-value pair, the key is passed through the hashing function of the hashtable, to gain an integer hash value. This is used as an index (Wrapped around using a modulus) to find the position of the hashtable entry.

The java Hashtable class is an implementation of an *open* hashtable, which means that when collisions occur, the hashtable uses *buckets* to store multiple entries (searched seququentially) under one index value. An example of this behaviour is when ("not", -42) is added.

The loadFactor variable is a measure of how full the hash table is allowed to get before its capacity is automatically increased. 0.75 (used here) is the default and offers 'a good tradeoff between time and space costs'. It's obvious to see that a lower load factor means that the array will be expanded more often, therefore there is less chance of a collision. However, the array is larger and takes up more space in memory. On the flipside, having a larger loadFactor means that the array will be expanded less often, resulting in less space in memory used, but larger chance for collisions to occur. This results in more buckets and sequential searches, diminishing the advantages the hashtable provides.

When the size of the array is dynamically increased, the entire array is rehashed. This explains the behaviour of the hashtable entries moving around when ("but", 999) is added. Rehashing is a relatively time consuming operation however. If a lot of entries are going to be made into the hashtable, then it can sometimes be better to create the hashtable with a larger initial capacity so that rehashing is less likely to occur.

The Java Hashtable documentation states that **no** rehashing will ever occur **if** the **initial capacity** is **greater than** the (**maximum entries to contain / load factor**)

The only danger of this is setting the initial capacity too high, which can waste space if a lot of duplicate entries are added.

Self Evaluation

I believe I provide more than just a sequence of screenshots, providing a step by step description then an extended analysis at the end of the exercise. I believe my analysis explains how internal array slots are allocated and provides a look at the differences in choice where loadFactor and initialCapacity are concerned. I believe my analysis is full and takes everything into consideration. Therefore, I would self-evaluate this week's exercises as a 5/5.

Practical 6 (Week 9)

(Logbook) Question 1: Complete the implementation of the binary tree class.

Code Listing

```
package binaryTree;
import java.util.ArrayList;
public class BinaryTree<T extends Comparable<? super T>> implements BTree<T> {
   private TreeNode<T> root; // the root node
   public BinaryTree() {
   public BinaryTree(T value) {
       root = new TreeNode(value);
    * @param left the tree's left subtree.
   public BinaryTree(T value,BinaryTree<T> left,BinaryTree<T> right) {
       root = new TreeNode(value,left,right);
```

```
public boolean isEmpty() {
* @param value the value to be inserted into the tree.
@Override
public void insert(T value) {
   if(isEmpty())
        root = new TreeNode<T>(value, new BinaryTree<>(), new BinaryTree<>());
   if(value.compareTo(this.getValue()) < 0)</pre>
       root.getRight().insert(value);
```

```
@Override
public T getValue() throws NullPointerException {
   if(isEmpty())
       throw new NullPointerException("Tree at current node is empty.");
* @param value the new value to be stored at the root of the tree.
@Override
public void setValue(T value) {
   if(isEmpty())
       root = new TreeNode<T>(value, new BinaryTree<>(), new BinaryTree<>());
```

```
@Override
public BTree<T> getLeft() throws NullPointerException {
   if(isEmpty())
       throw new NullPointerException("Current node is empty.");
@Override
public void setLeft(BTree<T> tree) {
@Override
public BTree<T> getRight() throws NullPointerException {
       throw new NullPointerException("Current node is empty.");
```

```
@Override
public void setRight(BTree<T> tree) {
@Override
   if(!isEmpty())
           return root.getLeft().contains(value);
           return root.getRight().contains(value);
```

```
public List<T> traverse() {
   ArrayList<T> list = new ArrayList<>();
   inOrderTraverse(this, list);
private void inOrderTraverse(BTree<T> tree, List<T> list)
   if(tree.isEmpty())
    inOrderTraverse(tree.getLeft(), list);
    list.add(tree.getValue());
   inOrderTraverse(tree.getRight(), list);
```

Testing class.

```
package binaryTreeTest;
import static org.junit.jupiter.api.Assertions.*;
public class BinaryTreeTest
   void testNullTreeConstructor()
       BinaryTree<Integer> intTree = new BinaryTree<>();
       if(!intTree.isEmpty())
           fail("Binary tree has not been created empty.");
           int x = intTree.getValue();
       catch(NullPointerException e){}
           BTree<Integer> leftTree = intTree.getLeft();
       catch(NullPointerException e){}
           BTree<Integer> rightTree = intTree.getRight();
           fail("Exception for trying to access right tree from null node not caught.");
       catch(NullPointerException e){}
```

```

       if(!Objects.equals(expectedList.get(x), returnedList.get(x)))
```

Test results.

Self Evaluation.

For 3 marks, I was asked to implement all methods, which I have done so. This qualifies me for 3 marks at the least. For 4 and 5 marks I was asked for good documentation and good testing. I don't think my documentation or testing are absolutely perfect, but given that the descriptor used is good, I would say my inclusion of testing and documentation is enough to qualify my work this week being 5/5

Practical 7 (Week 10)

(Logbook) Question 1: Implement the Traversal interface using depth-first traversal.

Code listing.

```
package graph;
import java.util.*;

/**
    * Created by u1661665(Joshua Pritchard) on 30/11/2018.
    * Version: 30/11/2018
    */
public class DepthFirstTraversal<T> extends AdjacencyGraph<T> implements Traversal<T>
{
    /**
         * Used to hold the list in which the nodes of the graph are traversed.
         */
         ArrayList<T> traversal;

         /**
          * A constructor for a depth first traversal that initializes the data structure used for the traversal list.
          */
    public DepthFirstTraversal()
          {
                traversal = new ArrayList<>();
          }
}
```

```
@Override
public List<T> traverse() throws GraphError
   T node = getUnvisitedNode();
       populateTraversal(getUnvisitedNode());
       node = getUnvisitedNode();
```

Testing class.

       fail("first pair not adjacent");
    else if(Math.abs((returnedList.get(2) - returnedList.get(3))) != 1)
       fail("Second pair not adjacent.");
```

```
}
else if(Math.abs(returnedList.get(4) - returnedList.get(5)) != 1)
{
    fail("Third pair not adjacent.");
}
```

```
* @throws GraphError if any attempt to access an invalid element of the graph is made.
   public void genericnessCircularGraphTest() throws GraphError
       DepthFirstTraversal<String> stringGraph = new DepthFirstTraversal<>();
       stringGraph.add("first");
       stringGraph.add("third");
       stringGraph.add("second", "third");
       ArrayList<String> returnedList = (ArrayList<String>) stringGraph.traverse();
       if (returnedList.qet(0).equals("first") && returnedList.qet(1).equals("second") && returnedList.qet(2).equals("third"))
       else if (returnedList.get(1).equals("first") && returnedList.get(2).equals("second") &&
returnedList.get(0).equals("third"))
           fail("Correct path not returned with a string graph");
```

Test results.

Self Evaluation.

The self evaluation criteria for 3 marks asks for a full implementation of the Depth-First traversal algorithm. I believe my implementation is full and works correctly returning a traversal list with no duplicated elements. Furthermore I believe that my re-use of the traversal list as a visited list removes space complexity and makes my implementation better.

For 4 and 5 marks I must have Javadoc documentation, which I have included, and full testing. Testing was difficult to develop for this due to the inherent difficulty in testing of graphs. This is because of their use of sets, which are not guaranteed to return the same element every time one is requested. This means complex graphs are very hard to test unless they have testable *properties* consistent across the entire graph. If none of these are present, testing a large, complex graph, would require hardcoding a test against every single possible result of the traversal.

This is long winded, repetitive and pointless considering that smaller graphs with intrinsic properties can be tested in the same way, meaning the more complex graphs will test fine as well.

I believe that my testing is full, adequate and covers all bases of the traversal method that may come into question.

Practical 8 (Week 11)

(Logbook) Question 1: Implement the TopologicalSort interface, using a depth first topological sort. The getSort() method should return a List(T), containing a topological sort of the nodes in the graph.

Code Listing.

```
@Override
public List<T> getSort() throws GraphError
   T noPredecessors = getNoPredecessorNode();
       sorted.add(noPredecessors);
       removeFromGraph(noPredecessors);
       noPredecessors = getNoPredecessorNode();
```

```
* @throws GraphError if any illegal attempts to access nodes or edges within this graph are made.
private void populateNodesMap() throws GraphError
    for(T node: getNodes())
```

```
* @return an element T contained within the graph that has no predecessors.
private T getNoPredecessorNode() throws GraphError
       if(nodes.get(node) == 0 && !sorted.contains(node))
       throw new GraphError("Graph not acyclic");
```

```
* Used by the sorter to remove a node from consideration i.e. prevent it being added to the graph twice and
  * decrease the reference count of all appropriate nodes.

* * @param node a T element specifying the node within the graph to remove.
  * @throws GraphError if any illegal attempts to access nodes or edges within the graph are made.

*/
private void removeFromGraph(T node) throws GraphError
{
    //For each successor of the passed in node.
    for(T successor: getNeighbours(node))
    {
        //Decrement the reference Count held against it in the hashmap by 1.
        nodes.replace(successor, nodes.get(successor) - 1);
    }
}
```

Note – I have chosen to leave the original implementation of populateNodesMap() in the code as a comment to show the progression from a less efficient version of the algorithm to a more efficient one.

Testing class.

```
mport graph.Graph;
mport graph.GraphError;
mport graph.ReferenceCountingTopologicalSort;
import static org.junit.Assert.fail;
public class RefCountTopoSortTest
   public void testContents() throws GraphError
       ReferenceCountingTopologicalSort<Integer> intSort = new ReferenceCountingTopologicalSort<>();
       intSort.add(1);
       intSort.add(2);
       intSort.add(3);
       intSort.add(4);
       intSort.add(1, 3);
       intSort.add(2, 4);
```

```
//
//Get the sort.
List<Integer> returned = intSort.getSort();

//Print the sort.
System.out.println(returned.toString());

//If any of the nodes are not contained within the sort, it's a fail.
if(!returned.contains(1))

   stringSort.add("Second", "Fourth");
   List<String> returned = stringSort.getSort();
       fail("First element is not 1.");
   if(returned.indexOf("Fourth") < returned.indexOf("Second"))</pre>
```

```
{
    fail("Index of Fourth is before index of Second.");
}
```

```
public void testCyclicGraphException() throws GraphError
   ReferenceCountingTopologicalSort<Integer> intSort = new ReferenceCountingTopologicalSort<>();
    intSort.add(2);
    intSort.add(3);
   intSort.add(4);
    intSort.add(1, 3);
    intSort.add(2, 4);
   intSort.add(4, 2);
       fail("Exception not thrown.");
```

}

Test results.

Self Evaluation

For 3 marks, a full implementation of the reference counting topological sort is expected, I have done this and further attempted to decrease the overall complexity of my implementation by refactoring code to be more efficient. This refactor also makes the code more readable and easier to maintain.

For 4/5 marks, full Javadoc documentation is expected, which I have included as usual, and full testing. I have done both of these, as evidenced by my code snippets above.
